SOLAR PRO. Active power capacitor

What is an active capacitor & auxiliary circuit?

An active capacitor can be integrated with the floating H-bridge power modules to remove the effect of the ripple powers on the DC bus. The auxiliary circuit, which is much smaller in size compared to an equivalent passive capacitor, helps increase the power density of the system.

What is an active capacitor?

The active capacitor is an additional circuit added to the system to absorb the fluctuating power to maintain a constant DC-link voltage. Since the fluctuating voltage allowed on the auxiliary circuit is large, the active capacitor's capacitance is much smaller than that of the traditional capacitor.

What is a two-terminal active capacitor?

a two-terminal active capacitor concept has been recently proposed in . Two-terminal active capacitors retain the same convenience of use as passive capacitors with two power terminalsonly, without any additional required connections of control signals and power supplies.

Can active capacitors be used in power electronic converters?

Power electronic converters implemented with the active capacitors could achieve either increased power density or reduced design cost for a given reliability specification, as discussed in . Several practical design issues need to be addressed to carry on the two-terminal active capacitor concept proposed in .

What is the difference between Passive DC-link capacitor and active capacitor?

With higher power rating, the efficiency of the system with passive DC-link capacitor is reduced, while the efficiency of the system with the active capacitor is increased.

What is the difference between active capacitor and passive capacitor?

The active capacitor is designed to absorb the ripple components in the DC side of the converters, which results in a constant DC-link voltage. In comparison to the passive capacitor solution, the active capacitor is much smaller in sizebut can give a better DC-bus ripple performance.

Capacitor power (Pc) represents the magnitude of this reactive power exchange. Capacitor power, P c(W) in watts is calculated by the product of current running through the capacitor, I c(A) in amperes and voltage running through the capacitor, V c(V) in volts.. Capacitor power, P c(W) = I c(A) * V c(V). P c(W) = capacitor power in watts, W.. V c(V) = voltage in volts, V.
