

What is the construction of a capacitor?

The construction of capacitor is very simple. A capacitor is made of two electrically conductive plates placed close to each other, but they do not touch each other. These conductive plates are normally made of materials such as aluminum, brass, or copper. The conductive plates of a capacitor are separated by a small distance.

How does a capacitor work?

Basically, a capacitor consists of two parallel conductive plates separated by insulating material. Due to this insulation between the conductive plates, the charge/current cannot flow between the plates and is retained at the plates.

How a capacitor is made?

As shown in the figure below, it is clearly visible that the capacitor is usually constructed by using two or more parallel conductive plates which are separated from each other by an insulating material. This insulating material is known as Dielectric.

Is a capacitor a conductive material?

This non-conductive material is called dielectric. The two conductive plates of the capacitor are good conductors of electricity. Therefore, they can easily pass the electric current through them. The conductive plates of the capacitor also hold the electric charge.

How to increase capacitance of a capacitor?

The capacitance of a capacitor can be increased in three ways such as Capacitors include dielectrics made from all kinds of materials. In transistor radios, the changing is carried out by a variable capacitor that has air in between its plates.

What determines the capacitance of a capacitor?

The capacitance of the capacitor mainly depends upon the surface area of each plate, the distance between two plates and the permittivity of the material between the two plates. Basic circuits of a capacitors mainly includes capacitors connected in series and capacitors connected in parallel.
