

Can transparent conductive electrodes be used for solar cells?

All in all, discovering means of production, development, and enhancement of transparent conductive electrodes will facilitate the advancement of transparent solar cells and thus a clean-energy society.

Why do solar cells need a transparent electrode?

A transparent electrode is essential for solar cells as it allows incoming light to reach the photoactive layer. Transparent conductive oxides (TCO) such as indium tin oxide (ITO) and fluorine doped tin oxide (FTO) are well-suited for this purpose due to their transparent and conductive nature.

How to choose a solar cell electrode?

Effects such as diffusion of elements from the electrodes to the internal layers, obstruction to moisture and oxygen, proper adhesion, and resistance to corrosion should also be taken under consideration. The choice of the electrodes also depends on the ETL or HTL materials used in the solar cells.

What metals are used in organic solar cells?

Ultrathin metals commonly used as the top electrode of transparent and semi-transparent organic solar cells have included silver, gold, aluminum, and copper.

Are electrodes used in perovskite solar cells?

This review aims to summarize the significant research work carried out in recent years and provide an extensive overview of the electrodes used till date in perovskite solar cells. We present a critical survey of the recent progress on the aspect of electrodes to be used in perovskite solar cells.

Which metals are used for back-contact electrodes in perovskite solar cells?

Metallic layers of Al, Au, and Ag have been reported to be used regularly for back-contact electrodes in the current advancements in perovskite solar cells. The metals with suitable work function and resistivity have been chosen as electrodes in PSCs.
