What are electrostatic capacitors?

Electrostatic capacitors dominates the market among the other capacitor technologies. The article provides introduction into construction of electrostatic capacitors, such as ceramic, film, paper technologies. Assembly styles, termination techniques or metallization processes are explained including impact to the basic parameters.

What is the construction of a capacitor?

The construction of capacitor is very simple. A capacitor is made of two electrically conductive plates placed close to each other, but they do not touch each other. These conductive plates are normally made of materials such as aluminum, brass, or copper. The conductive plates of a capacitor are separated by a small distance.

How a capacitor is made up of two conductive electrodes?

A capacitor is usually made up of two conductive electrodes in which an insulating material called dielectric separates them as shown in (Fig. 9.6). Applied voltage causes electric charge to be gathered on the surface of the electrodes which are isolated by the dielectric layer, hence, generating an electric field.

What is a ceramic capacitor?

Advent of ICs, computers, electronic devices, mobile phones and other portable electronic devices gave a big impetus to ceramic capacitor market. Ceramic capacitors are fixed value capacitors with ceramic materials as dielectric. Two types of ceramic are in common use - disc capacitors and multilayer ceramic capacitors (MLCC).

What types of capacitors are used in electronic devices?

Film and ceramic capacitors and electrolytic capacitors (Section 8.2.2) are the most common capacitors in electronic devices. There are various types of film capacitors with varying dielectric materials.

What is a dielectric capacitor?

A conventional dielectric capacitor generally consists of two electrodes with a thin layer of dielectric material in between them. Thin dielectric materials whose two opposite surfaces are coated with conducting paste constitute a dielectric capacitor.
