What is capacitor charge storage?

Capacitive charge storage is well-known for electric double layer capacitors (EDLC). EDLCs store electrical energy through the electrostatic separation of charge at the electrochemical interface between electrode and electrolyte, without involving the transfer of charges across the interface.

What is capacitive charge storage?

As shown in Figure 1, capacitive charge storage entails a physical charge separation at the electrochemical electrode-electrolyte interface. Importantly, no electrons are transferred across this interface.

How can a charge storage perspective be used to design electrochemical interfaces?

This perspective can be used as a guide to quantitatively disentangle and correctly identify charge storage mechanisms and to design electrochemical interfaces and materials with targeted performance metrics for a multitude of electrochemical devices.

What is the current-time scaling for capacitive charge storage?

The current-time scaling for capacitive charge storage can be determined analogue to the derivation of the faradaic diffusion-limited current-time scaling. The detailed derivation can be found in S2 of the Supporting Information.

What is the current-time scaling for pseudocapacitive charge storage?

The current-time scaling for pseudocapacitive charge storage will be derived like the faradaic diffusion-limited charge storage (Equations (4)–(10)), however, the molar flux of the electroactive species at the electrochemical interface is determined by a combination of a small diffusion zone,  $\delta$ , and more dominant migration zone,  $d$ . (Figure 1B).

Can energy storage systems bridge the gap between high specific energy and power?

Researchers developing the next generation of energy storage systems are challenged to understand and analyze the different charge storage mechanisms, and subsequently use this understanding to design and control materials and devices that bridge the gap between high specific energy and power at a target cycle life.

Supercapacitors typically operate based on the principle of electrical double-layer capacitance (C<sub>EDL</sub>) and pseudo capacitance. The charging process, ions from the electrolyte are adsorbed onto the positive and negative surfaces of the electrodes, forming an electrical double-layer under the influence of an external voltage difference.

106 Z. Yang et al. The network resistance power loss is calculated by:  $P_{TR} = I_2^2 R_{TMS} \cdot R_T$  (6) where  $I_{2RMS}$  represents the source-side current and  $R_T$  is the network resistance. The diodes power loss in one cycle is:  $P_{VD4} = 4 \cdot I_{2RMS}^2 \cdot r_T$  (7) where  $r_T$  is the diode resistance. Ignoring the capacitor power loss, the active power loss of the load is obtained
