

Do lithium-ion batteries release smoke gas during thermal runaway?

By analyzing the smoke gas emission, this work has shown that 100 % charged cylindrical lithium-ion batteries release a likely smoke gas quantity of up to 27 mmol Wh⁻¹ during the thermal runaway (see Fig. 5). Individual, unverifiable measurements even yield values of up to 48 mmol Wh⁻¹.

How much heat does a 100 % charged Lib produce?

The more closely examined values show that a 100 % charged LIB can produce a peak heat release rate of 1.8 kW Wh⁻¹ for cylindrical cells, 2.6 kW Wh⁻¹ for pouch cells and 2.8 kW Wh⁻¹ for prismatic cells in the event of a thermal runaway (see Fig. 2).

Why are flammable gases important in battery research?

Production of toxic and flammable gases During the TR of a LIB, considerable amounts of numerous smoke gases are produced, which have an increasing importance in battery research due to their combustibility, toxicity and/or asphyxiating effect on the human organism.

Does SoC affect the gas composition of thermally abused batteries?

Diaz et al. conclude that the gas composition of thermally abused batteries varies with its SOC. Accordingly, HF is more stable at low SOC than at high SOC, where formation of other undetected fluorides such as tetrafluoromethanes (CF₄) may occur.

Do high environmental pressure batteries increase unit growth rate of combustion heat?

Their key finding is that the batteries at high environmental pressure have a greater unit growth rate of combustion heat for every 1 % increase in SOC. Two of the publications considered are by Ouyang et al.

Why does a cell have more combustible gases?

One reason for this could be the increasing amount of combustible gases and oxygen accumulating inside the cell during TR. Chen et al. and Wang et al. referred that large amounts of gas accumulate inside the cell at higher states of charge.
