

# Hard carbon negative electrode materials for lithium batteries

What materials are used for negative electrodes?

Carbon materials, including graphite, hard carbon, soft carbon, graphene, and carbon nanotubes, are widely used as high-performance negative electrodes for sodium-ion and potassium-ion batteries (SIBs and PIBs).

Can biomass-based hard carbon anodes be used for lithium-ion batteries?

Synthesis of biomass-based hard carbon anodes for lithium-ion batteries is reported. Spruce is used as biomass, and the anodes are prepared by an electrochemical pre-lithiation for full-cell operation. Lithium-ion full-cells based on pre-lithiated anodes show significantly improved performance than pristine anode-based full-cells.

Is hard carbon a good anode for lithium ion batteries?

Volume 5, Issue 3, 20 March 2024, 101851 Due to its overall performance, hard carbon (HC) is a promising anode for rechargeable lithium-, sodium-, and potassium-ion batteries (LIBs, NIBs, KIBs).

Are lithium-ion battery full-cells based on Spruce-derived hard carbon anodes lithiated?

In this work, lithium-ion battery full-cells based on spruce-derived hard carbon anodes and an electrochemical pre-lithiation method are presented in combination with a detailed analysis of full-cell operation and the lithiation state. The physical and electrochemical properties agree well with those of previous biomass-derived hard carbon anodes.

Is graphite a good anode material for lithium ion batteries?

Graphite has long served as the industry standard for the state-of-the-art anode material for lithium-ion batteries (LIBs). However, it reaches its theoretical limits (low capacity high voltage hysteresis during the delithiation process) and might not keep up with the increasing demand for high-energy-density and high-power LIBs.

Can spruce hard carbon replace graphite in lithium-ion battery anodes?

With its comparably high capacity, rate capability and capacity retention, spruce hard carbon is a promising candidate to replace conventional graphite in lithium-ion battery anodes. However, it must be noted that the full-cells have capacities and a capacity decay that do not yet meet industrial standards.

Due to its abundant and inexpensive availability, sodium has been considered for powering batteries instead of lithium; hence, sodium-ion batteries are proposed as replacements for lithium-ion batteries. New types of negative electrodes that are carbon-based are studied to improve the electrochemical performance and cycle life of sodium cells. ...

A first review of hard carbon materials as negative electrodes for sodium ion batteries is presented, covering

not only the electrochemical performance but also the synthetic methods and microstructures. The relation between the ...

In the case of carbon-based lithium ion batteries, lithiated carbon is a powerful reducing agent (negative electrode) whereas a metal oxide constitutes the oxydant positive electrode. As the battery is assembled with profit in the discharged state where the active materials present low reactivity to the environment, it is the positive material that has to be in a ...

Hard carbon is conducive to the insertion of lithium without causing significant expansion of the structure, and has good charge and discharge cycle performance. Hard ...

Graphite has long served as the industry standard for the state-of-the-art anode material for lithium-ion batteries (LIBs). However, it reaches its theoretical limits (low capacity high voltage hysteresis during the delithiation process) and might not keep up with the increasing demand for high-energy-density and high-power LIBs [1]. Hard-carbon (non-graphitizable ...

Moreover, even though a sodium-ion battery with this hard carbon negative electrode would in theory operate at a 0.3-volt lower voltage difference than a standard lithium-ion battery, the higher ...

Among numerous negative electrode (anode) materials [2] for PIBs the carbon-based ones attract much attention as they deliver high electronic conductivity and promising electrochemical characteristics at relatively low cost. However, graphite used for Li-ion batteries demonstrates huge volume expansion about 60% [3] in PIBs impeding its practical application.

Historically, research on the negative electrode hosts for rocking-chair batteries goes back to mid-1980s, when carbonaceous materials were found to be promising candidates for Li intercalation [5, 6] fore addressing the solvent co-intercalation issue in graphite, disordered carbons (e.g., soft and hard carbons) were the first candidates tested as the anode or negative ...

With the development of high-performance electrode materials, sodium-ion batteries have been extensively studied and could potentially be applied in various fields to replace the lithium-ion cells, owing to the low cost and natural abundance. ... 2. The Mechanism of Sodium Storage in Hard Carbons. The main working principle of a Na-ion battery is based on the embedding and detachment of Na + ions into and from the electrodes. Because the storage of Na + ions mainly depends on the microstructure of the hard carbons, the storage mechanisms of different carbon
