

## Reasons for overheating of new energy storage charging piles

What causes a battery to overheat?

Causes of overheating include the rate of: Battery age/degradation. Internal resistance and electrochemical reactions in the battery mean that heat is generated by charging and discharging and will increase with the current flowing through the battery. This is a typical operating characteristic, and the BTMS should be designed to mitigate for it.

What happens if battery cell temperature is too high?

If the battery cell temperatures get extremely high, it can cause more rapid degradation. Mechanisms include separator tearing due to temperature gradients, dendrite formation, and associated separator piercing. At extremely high temperatures, electrolyte off-gassing and separator collapse present the risk of thermal runaway.

How does weather affect a battery?

Extreme weather events are increasingly pushing operating conditions out of design parameters and increasing the risk of battery failure. When a combination of ambient temperature, battery age, and rate of charge result in overheating, the battery management system may limit the discharge rate and depth, or the charge rate, to protect the battery.
